Description

FIELD OF THE INVENTION

This invention relates to a birefringence polarizer, and more particularly to a grating type polarizer based on different diffraction efficiencies depending on the direction of polarization.

BACKGROUND OF THE INVENTION

A polarizer element, particularly a polarizing beam splitter, is an element in which a specific polarized light is obtained at different angles of propagation which depend on the direction of polarization of two orthogonally polarized components of an incident light.

Conventional polarizing beam splitters, such as Glan-Thompson prism or Rochon prism, include an element using a crystal with enhanced birefringence in which a light path is split due to the difference between refraction angles or total reflection angles of two orthogonally polarized components of light at the reflection plane of the crystal with enhanced birefringence, as well as an element using a total reflection prism which consists of an isotropic optical medium such as glass and provided with a multilayer dielectric film formed on the reflection plane thereof whereby light is totally reflected, or otherwise transmitted, in accordance with refractive indices of polarized components.

These conventional elements, however, have a disadvantage that they are large in size, low in production efficiency and expensive.

The reflection boundary surface in these conventional elements is positioned to be slant by at least 45 degrees relative to the light axis. Therefore, such an element has to take the form of a cube having a side no less than $\sqrt{2}$ times a diameter of the light beam to be transmitted. Specifically, the side of the cube is as long as 8 to 10 mm where the conventional polarizer element is applied to an optical disc recording or reproducing apparatus.

Another type of a conventional polarizer element is disclosed in "National conference record, 1982, Optical & Radio Wave Electronics, the Institute of Electronics & Communication Engineers of Japan, Part 2". The conventional polarizer element consists of a birefringent tapered plate of Rutile (TiO_2) having a tapered angle of 4 degrees. When parallel light beam is incident to the birefringent tapered plate on one side thereof, the parallel light beam is subject to different refractions between an extraordinary ray component and an ordinary ray component, so that the two components are split on the other side of the birefringent tapered plate with a split angle of approximately 1

degree.

The birefringent tapered plate, however, is associated with a disadvantage that a fabricating process is complicated, because the cutting of a tapered configuration is difficult on a mass-production basis, and the polishing of tapered surfaces is also difficult to be carried out. There is a further disadvantage that Rutile is expensive.

JP-A-63 055 501 discloses a polarizer according to the preamble of present claim 1.

SUMMARY OF THE INVENTION

According to the invention, a birefringence diffraction grating type polarizer comprises:

an optically anisotropic sheet crystal substrate provided with periodical ion-exchanged regions on the principal plane thereof to form an optical diffraction grating,

dielectric layers each provided on each of the ion-exchanged regions, and

a metal diffusion layer in which metal is diffused in the vicinity of the surface of the crystal substrate at least within the regions where the ion-exchange is effected on the crystal substrate.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention will be explained in more detail in conjunction with appended drawings wherein,

Fig. 1 is a cross-sectional view showing a birefringence diffraction grating type polarizer in an embodiment according to the invention, and

Fig. 2 is a perspective view of the polarizer of Fig. 1.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Before explaining a birefringence polarizer in an embodiment according to the invention, the principle and the feature of the invention will be briefly explained.

A birefringence diffraction grating type polarizer according to the invention is composed of an optically anisotropic crystal substrate which is provided, on the principal plane parallel to its optical axis, with a series of ion-exchanged regions, each of which is provided with a dielectric layer deposited thereon, whereby a light path is split due to the difference in diffraction efficiencies.

The refractive index within ion-exchanged regions provided periodically on the principal plane of, for example, a lithium niobate crystal substrate, is changed due to the ion-exchange as much as +0.10 for the ordinary ray and -0.04 for the extraordinary ray at the wavelength of 1.3 μm . Therefore, if the decrease in the refractive index for the

ordinary ray within the ion-exchanged region is compensated by increasing the thickness of the dielectric layer on the ion-exchanged region, both the diffraction efficiency of first or higher order for the ordinary ray and the zero order diffraction efficiency for the extraordinary ray can be made null, so that a polarizer is formed.

It is found, however, that distortion of crystal lattice is sometimes caused by the ion-exchange on the substrate. As a result, a linearly polarized incident light becomes an elliptically polarized light, thereby resulting in degradation of an extinction ratio. For this reason, a high extinction ratio is not obtained, even if polarizers of this type are arranged in tandem, or where an optical isolator is composed in the combination of the polarizer with a Faraday rotor.

The polarizer according to the invention is prevented from the distortion of crystal lattice caused by the ion-exchange by means of a metal diffused layer near the surface of the crystal surface, consequently, it is avoided that a linearly polarized incident light becomes an elliptical polarized light. That is, the crystal lattice is subject to distortion in an opposite direction to that in the ion-exchange by the diffusion of metal thereinto, where an orientation of the crystal substrate and a kind of the metal are appropriately selected. Accordingly, the distortion of the crystal lattice caused by the metal diffusion and that of the crystal lattice caused by the ion-exchange are canceled each other to avoid the distortion of the crystal lattice. Therefore, a birefringence diffraction grating type polarizer having a high extinction ratio and a minimized insertion loss is obtained.

A birefringence diffraction grating type polarizer in an embodiment according to the invention will be explained referring to Figs. 1 and 2. A crystal substrate 1 having optical anisotropy is, in this embodiment, a Y cut crystal sheet of lithium niobate (LiNbO_3). A series of proton-exchanged regions 3 are provided periodically on the substrate 1. Each of these proton-exchanged regions 3 is provided with a dielectric film 4 of a required thickness deposited thereon to form an optical diffraction grating. A metal diffusion layer 2 is formed covering the upper surface of the substrate 1.

As shown in Fig. 2, an incident light 10 of circular polarization is split to a zero order diffraction light 11 polarized in the x-axis, a plus first order diffraction light 12 and a minus first order diffraction light 13, such that the latter two lights are polarized orthogonally to the polarization of the zero order light 11.

The intensity of the zero order diffraction light from the diffraction grating, i.e. the diffraction efficiency, as shown in Fig. 1 and Fig. 2 is given by the equation

$$\cos^2\{\pi[\Delta n T_p + (n_d - 1)T_d]/\lambda\}$$

where λ represents a wavelength of light, Δn represents the change in the refractive index by the proton-exchange, T_p represents a depth of the proton-exchanged regions 3, n_d represents a refractive index of the dielectric film 4, and T_d represents a thickness of the dielectric film 4. If a wavelength of light is $1.3\mu\text{m}$, the change in the refractive index due to the proton-exchange is about +0.10 for the ordinary ray and about -0.04 for the extraordinary ray.

If a film of niobium oxide (Nb_2O_5) having a refractive index of approximately 2.2 is used for the dielectric film 4, the proton-exchanged region 3 of about $4.6\mu\text{m}$ in depth and the niobium oxide film of 160nm in thickness cause the zero-order diffraction efficiency for the extraordinary ray to be zero and the zero-order diffraction efficiency for the ordinary ray to be 1, so that the element functions as a polarizer.

The polarizer according to the invention is fabricated by

- (1) depositing a metal film on a crystal substrate 1 having an optical anisotropy such as lithium niobate etc. by means of sputtering, electron beam evaporation or the like,
- (2) providing a metal diffusion layer 2 having the approximately same depth as that of proton-exchanged regions 3 by heating in an electric furnace, and where the metal is titanium, diffusing titanium thermally by heating the substrate at about 1000°C or higher for several hours, for example at 1050°C for 8 hours, to form titanium diffusion layer 2 in accordance with a deposited titanium film of a 30 nm thickness,
- (3) forming a mask in the form of a grating over the substrate 1 by a conventional lithographic technology or the like,
- (4) immersing the crystal substrate with the mask in an acid at the temperature of 200°C or higher for several hours, for example, in benzoic acid at 249°C for four and half hours, to form proton-exchanged regions 3, and
- (5) forming a dielectric film 4 on each of the proton-exchanged regions 3.

In forming the dielectric film 4, a sputtering process in which niobium oxide (Nb_2O_5) is used for a target, or a reactive sputtering process in which Nb is used for a target in an atmosphere of O_2 is carried out to provide a grown film, and an ordinary lithographic technology is utilized to provide a predetermined pattern, where niobium oxide (Nb_2O_5) is used for the dielectric film 4. If required, an anti-reflection film is provided on both the dielectric film 4 and a region in which the dielectric film 4 is not provided. The anti-reflection film is provided in the

form of an SiO₂ film having a thickness of approximately 220 nm and a refractive index of approximately 1.5 by an ordinary sputtering process, where the anti-reflection film faces, for instance, the air.

In a polarizer according to the invention, a diffraction angle is inversely proportional to a pitch of a diffraction grating. Therefore, the pitch is determined, such that the diffraction angle is more than a predetermined separation angle. For instance, a first order diffraction angle is 0.74°, where the pitch is 100 μm at a light wavelength of 1.3 μm, and the first order diffraction angle is 7.5°, where the pitch is 10 μm at the same wavelength.

Where a Y plate of lithium niobate is diffused with titanium, crystal lattice is subject to distortion in an opposite direction to that in the ion-exchange as described before. Therefore, the distortion of the crystal lattice caused by a metal diffusion and that of the crystal lattice caused by the ion-exchange are canceled each other, thereby avoiding the distortion of the crystal lattice. Accordingly, either an ordinary or extraordinary ray split in a polarizer according to the invention is avoided to be elliptically polarized. This provides a polarizer having a very high extinction ratio, where polarizers of the invention are in a tandem arrangement, and an isolator having a high extinction ratio, where the isolator is provided in the combination of the polarizer with a Faraday rotor.

The diffusion of metal such as titanium may be restricted to proton-exchanged regions, though titanium is diffused on the whole surface of the substrate in the described embodiment. Copper, nickel, vanadium, magnesium or the like may be used in place of titanium in the metal diffusion layer 2.

According to the invention, a polarizer in a thin form can be obtained at a low cost, since it can be fabricated from a thin lithium niobate sheet crystal in quantities by batch process, and the polarizer provides a high extinction ratio and a low insertion loss.

Although the invention has been described with respect to specific embodiment for complete and clear disclosure, the appended claims are not to thus limited but are to be construed as embodying all modification and alternative constructions that may occur to one skilled in the art which fairly fall within the basic teaching herein set forth.

Claims

1. A birefringence diffraction grating type polarizer, comprising:
an optically anisotropic sheet crystal substrate (1) provided with periodical ion-exchanged regions (3) on one surface thereof to

form an optical diffraction grating;

said polarizer being characterised by
a dielectric layer (4) on each of said ion-exchanged regions; and

a metal diffusion layer (2) created by diffusion of metal into said one surface of said crystal substrate at least within regions where ion-exchange is effected on said crystal substrate.

2. A birefringence diffraction grating type polarizer as defined in claim 1,
wherein said metal diffusion layer is provided on the whole of said one surface of said crystal substrate.
3. A birefringence diffraction grating type polarizer as defined in claim 1,
wherein said crystal substrate is composed of lithium niobate.
4. A birefringence diffraction grating type polarizer as defined in claim 1,
wherein said metal is selected from the group consisting of titanium, copper, nickel and vanadium.
5. A birefringence diffraction grating type polarizer as defined in claim 1,
wherein said dielectric layer is composed of quartz.
6. A birefringence diffraction grating type polarizer as defined in claim 1,
wherein said ion-exchanged region is a proton-exchanged region.
7. A birefringence diffraction grating type polarizer as defined in claim 1,
wherein a depth of said ion-exchanged region and a thickness of said dielectric layer is selected so as to cause the zero-order diffraction efficiency for the extraordinary ray to be zero and the zero-order diffraction efficiency for the ordinary ray to be 1.

Patentansprüche

1. Polarisator vom Typ eines doppelbrechenden Beugungsgitters mit:
einem optischen anisotropen Schichtkristallsubstrat (1), mit auf einer Oberfläche vorgesehenen periodischen ionenausgetauschten Bereichen (3), die ein optisches Beugungsgitter bilden,
wobei der Polarisator gekennzeichnet ist durch eine dielektrische Schicht (4) auf jedem der ionenausgetauschten Bereiche, und

- eine Metaldiffusionsschicht (2), die durch Diffusion von Metall in die eine g nannte Fläche des Kristallsubstrats mindestens innerhalb der Bereiche erzeugt wird, in denen ein Ionenaustausch auf dem Kristallsubstrat bewirkt wird.
2. Polarisator vom Typ eines doppelbrechenden Beugungsgitters nach Anspruch 1, wobei die Metaldiffusionsschicht auf der gesamten genannten Fläche des Kristallsubstrats vorgesehen ist.
 3. Polarisator vom Typ eines doppelbrechenden Beugungsgitters nach Anspruch 1, wobei das Kristallsubstrat aus Lithiumniobat zusammengesetzt ist.
 4. Polarisator vom Typ eines doppelbrechenden Beugungsgitters nach Anspruch 1, wobei das Metall ausgewählt ist aus der Gruppe bestehend aus Titan, Kupfer, Nickel und Vanadium.
 5. Polarisator vom Typ eines doppelbrechenden Beugungsgitters nach Anspruch 1, wobei die dielektrische Schicht aus Quarz zusammengesetzt ist.
 6. Polarisator vom Typ eines doppelbrechenden Beugungsgitters nach Anspruch 1, wobei der ionenausgetauschte Bereich ein protonenausgetauschter Bereich ist.
 7. Polarisator vom Typ eines doppelbrechenden Beugungsgitters nach Anspruch 1, wobei eine Tiefe des ionenausgetauschten Bereichs und eine Breite der dielektrischen Schicht so ausgewählt ist, daß die Beugungswirksamkeit 0ter Ordnung für den außerordentlichen Strahl 0 wird und die Beugungswirksamkeit 0ter Ordnung für den ordentlichen Strahl 1 ist.
- Revendications**
1. Un polariseur de type de réseau de diffraction biréfringent, comprenant:
 - un substrat cristallin à feuille optiquement anisotrope (1) doté de régions échangeuses d'ions périodiques (3) sur l'une de ses surfaces pour former un réseau de diffraction;
 - ledit polariseur étant caractérisé par
 - une couche diélectrique (4) sur chacune desdites régions échangeuses d'ions; et
 - une couche de diffusion de métal (2) créée par diffusion du métal dans ladite surface dudit substrat cristallin au moins dans les régions où l'échange d'ions intervient sur ledit substrat
 2. Un polariseur de type de réseau de diffraction biréfringent tel qu'il est défini à la revendication 1,
 - dans lequel la couche de diffusion de métal est disposée sur la totalité de ladite surface dudit substrat cristallin.
 3. Un polariseur de type de réseau de diffraction biréfringent tel qu'il est défini à la revendication 1,
 - dans lequel ledit substrat cristallin est composé de niobate de lithium.
 4. Un polariseur de type de réseau de diffraction biréfringent tel qu'il est défini à la revendication 1,
 - dans lequel ledit métal est sélectionné dans le groupe consistant de titane, cuivre, nickel et vanadium.
 5. Un polariseur de type de réseau de diffraction biréfringent tel qu'il est défini à la revendication 1,
 - dans lequel ladite couche diélectrique est composée de cristal.
 6. Un polariseur de type de réseau de diffraction biréfringent tel qu'il est défini à la revendication 1,
 - dans lequel ladite région échangeuse d'ions est une région échangeuse de protons.
 7. Un polariseur de type de réseau de diffraction biréfringent tel qu'il est défini à la revendication 1,
 - dans lequel une profondeur de ladite région échangeuse d'ions et une épaisseur de ladite couche diélectrique est choisie de manière à causer l'efficacité de diffraction d'ordre zéro pour que le rayon extraordinaire soit zéro et l'efficacité de diffraction d'ordre zéro pour que le rayon ordinaire soit 1.
